

Rak v Sloveniji

Za dodatne podatke o bremenu raka v Sloveniji in svetu obiščite www.slora.si.

- Med rojenimi leta 2021 bosta do svojega 75. leta starosti za rakom predvidoma zbolela eden od dveh moških in ena od treh žensk.
- Za rakom zboli letno približno 17.000 Slovencev, več kot 9.000 moških in skoraj 8.000 žensk, umre pa jih več kot 6.000, približno 3.500 moških in 2.500 žensk; med nami živi že več kot 130.000 ljudi, ki so kadarkoli zboleli zaradi ene od rakavih bolezni (prevalenca).
- Število novo zbolelih leta 2021, v drugem letu epidemije Covid-19, je precej višje v primerjavi s prvim letom epidemije, vseeno pa primankljaja iz leta 2020 nismo nadoknadili.
- Ogroženost z rakom je največja pri starejših; med vsemi bolniki z rakom, zbolelimi leta 2021, je bilo 66 % starejših od 65 let. Ker se slovensko prebivalstvo stara, je samo zaradi vedno večjega deleža starejših pričakovati, da se bo število novih primerov raka še večalo.
- Najpogostejši raki pri nas (kože, pljuč, dojk, prostate ter debelega črevesa in danke) so leta 2021 predstavljali 60 % vseh ugotovljenih rakov. Ti raki so povezani z nezdravim življenjskim slogom: kajenjem, pitjem alkoholnih pijač, neustrezno prehrano, premalo gibanja in prekomerno težo ter izpostavljenostjo soncu. Ogroženost z njimi lahko zmanjšamo z ukrepi primarne preventive.
- Presejalni programi za rake, ki jih priporoča Svet Evropske unije in smo jih uvedli tudi v Sloveniji, lahko z zgodnjim odkrivanjem zmanjšajo umrljivost za rakom dojk, debelega črevesa in danke ter rakom materničnega vratu; pri slednjih dveh že več let opazujemo tudi zmanjšanje incidence.
- Petletno čisto preživetje odraslih slovenskih bolnikov s katerokoli vrsto raka (brez nemelanomskega kožnega), ki so zboleli v obdobju 2017–2021, je bilo 58 %, bolnic pa 63 %.

Povzetek

Figure 1. Cancer burden, Slovenia 2021.

Osnovni podatki o raku v Sloveniji 2021

- Leta 2021 je v Sloveniji za rakom zbolelo 17.288 ljudi (9.319 moških in 7.969 žensk).
- Starostno standardizirana incidenčna stopnja (evropsko prebivalstvo) je bila 516,9/100.000; 598,0 pri moških in 459,2 pri ženskah. Med rojenimi leta 2021 bosta do svojega 75. leta starosti za rakom predvidoma zbolela eden od dveh moških in ena od treh žensk.
- Leta 2021 je za rakom umrlo 6.213 Slovencev, 3.555 moških in 2.658 žensk. Med nami je živel 130.642 ljudi (60.567 moških in 70.075 žensk), ki so kadarkoli zboleli za eno od rakavih bolezni (prevalenca).
- Med posameznimi slovenskimi regijami ne opažamo bistvenih razlik v bremenu raka.

Starost bolnikov

- Čeprav se ogroženost z rakom zmeroma večja, je največja v poznejši starosti; med vsemi onkološkimi bolniki je leta 2021 kar 69 % moških in 64 % žensk zbolelo po dopolnjeni starosti 65 let. Polovica odstotka vseh rakavih bolezni je bilo ugotovljenih pri otrocih in mladostnikih (do 20. leta).
- Ker se slovensko prebivalstvo stara, je samo zaradi čedalje večjega deleža starejših pričakovati, da se bo število novih primerov raka še večalo. Ocenjujemo, da bomo leta 2024 zabeležili že 17.971 novih bolnikov.

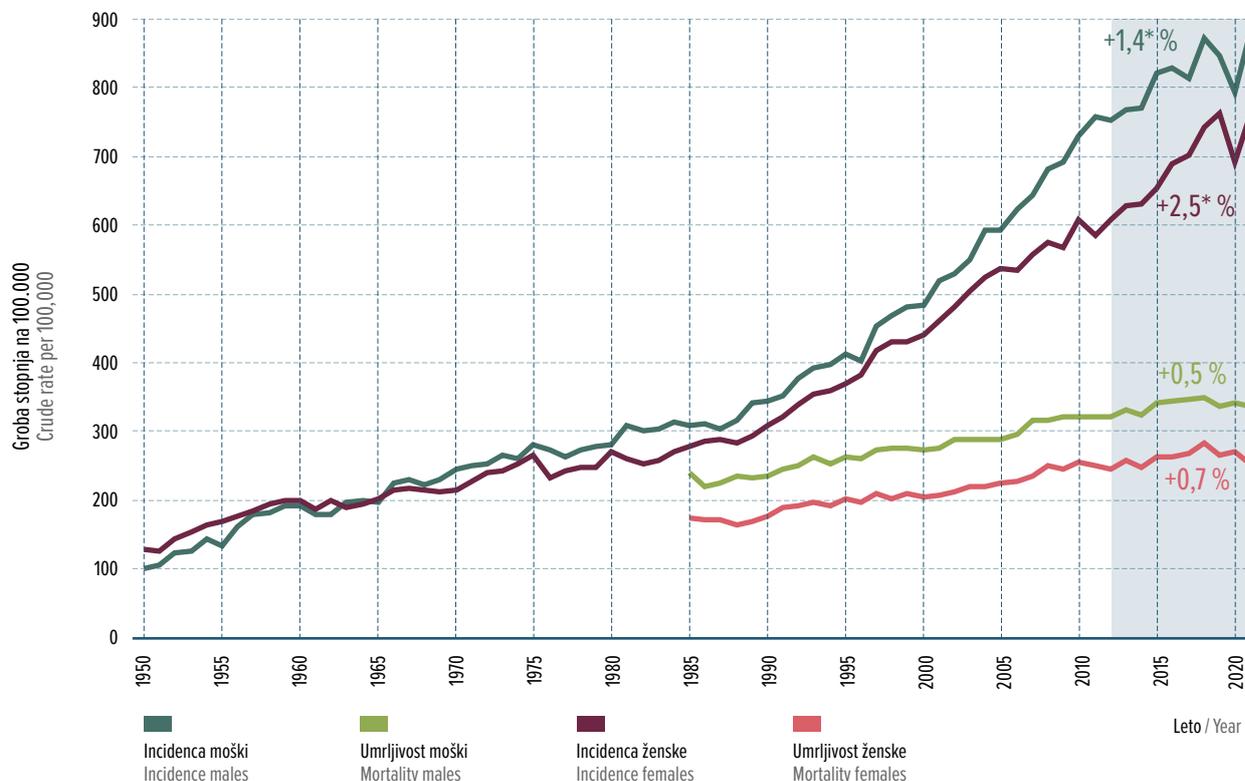

Slika 2. Število novih primerov vseh rakov (desna stran) po starosti ter primerjava s številom prebivalcev (leva stran) v istih starostnih skupinah, Slovenija 2021.

Časovni trend

- V splošnem se groba incidenčna in umrljivostna stopnja raka večata. Število novo zbolelih leta 2021, v drugem letu epidemije Covid-19, je precej višje v primerjavi s prvim letom epidemije.
- Groba incidenčna stopnja se je v zadnjih 20 letih skoraj podvojila, v zadnjem desetletju se večja za 1,9 % povprečno letno (1,4 % pri moških in 2,5 % pri ženskah). Groba umrljivostna stopnja se je pri moških v zadnjih 10 letih večala povprečno za 0,5 % letno, pri ženskah pa za 0,7 %.
- Več kot polovico tega povečanja lahko pripišemo staranju prebivalstva, saj z daljšo življenjsko dobo lahko tudi več ljudi dočaka to bolezen. Starostno standardizirana kumulativna incidenčna stopnja kaže, da se tveganje raka večja počasneje, pri moških se trend celo obrača navzdol. Spodbudno je tudi, da se umrljivost zaradi raka (če ne upoštevamo staranja prebivalstva) manjša, predvsem od sredine devetdesetih let, kar kaže na večjo uspešnost zdravljenja.

* Povprečna letna sprememba je statistično značilna pri stopnji tveganja 0,05 / Average annual change is statistically significant at 0.05 significance level

Najpogostejši raki

- Rak ni ena sama bolezen, temveč več sto različnih. Te lahko vzniknejo v vseh tkivih in organih človeškega organizma. Razlikujejo se po pogostosti, zdravljenju in izidu, imajo pa tudi različne bolj ali manj znane nevarnostne dejavnike.
- Pet najpogostejših vrst raka pri nas – kožni (brez melanoma), prostate, pljuč, dojk, ter raki debelega črevesa in danke – obsega 60 % vseh novih primerov rakavih bolezni.
- Najpogostejši raki so povezani z nezdravim življenjskim slogom: kajenjem, pitjem alkoholnih pijač, neustrezno prehrano, premalo gibanja in prekomerno težo ter izpostavljenostjo soncu. Ogroženost z njimi lahko zmanjšamo z ukrepi primarne preventive.
- Pri moških zavzemata nemelanomski kožni rak in rak prostate vsak približno petino vseh rakov, sledita pljučni rak ter rak debelega črevesa in danke. Pri ženskah je najpogostejši nemelanomski kožni rak, sledi rak dojk, ki predstavlja približno petino vseh rakov, nato pa še pljučni rak ter rak debelega črevesa in danke.
- Najpogostejši raki se v različnih življenjskih obdobjih pojavljajo različno. Pri otrocih in mladostnikih do 20. leta starosti so najpogostejše levkemije, sledijo jim tumorji centralnega in avtonomnega živčnega sistema in limfomi. Mlajši odrasli (20–49 let) moški zbolevajo največ za rakom mod in kože, pri ženskah v tej starosti pa je na prvem mestu rak dojk.

Trend najpogostejših rakov

- Med pogostejšimi rakavimi boleznimi pri moških se je incidenčna stopnja pljučnega raka večala vse do začetka novega tisočletja, ko se je ustalila pri vrednosti okoli 90/100.000.
- Pljučnega raka sta v novem tisočletju prehitela rak prostate in nemelanomski kožni rak, ki se še vedno večja za povprečno povprečno 5 % letno. Izjemno povečanje incidence raka prostate v zadnjih dveh desetletjih ni posledica kakšnega novega nevarnostnega dejavnika, temveč predvsem vse širše rabe testa za določanje za prostato specifičnega antigena (PSA) pri moških brez zdravstvenih težav in odkrivanja velikega števila primerov, ki bi sicer ostali vse življenje prikriti. Podatki za zadnja leta kažejo, da smo vrh incidence raka prostate že dosegli.
- Tudi časovne spremembe v pojavljanju raka debelega črevesa in danke je treba ocenjevati ob upoštevanju sprememb v diagnostiki – leta 2009 smo namreč v Sloveniji uvedli Državni program presejanja in zgodnjega odkrivanja predrakavih sprememb in raka na debelem črevesu in danki (Svit). Groba incidenčna stopnja raka debelega črevesa in danke pri moških od leta 2012 pada za 1,9 % letno, pred tem pa je v desetletnem obdobju 1999–2008 naraščala vsako leto za 3,6 %. Povprečne letne odstotne spremembe so prikazane ob krivuljah na Sliki 7a.
- Med pogostejšimi rakavimi boleznimi pri ženskah so se večale grobe incidenčne stopnje raka dojke (za 1,9 % povprečno letno), nemelanomskega kožnega raka (povečanje za povprečno 5,3 % letno), pljučnega raka (za 6,0 %), kožnega melanoma (2,7 %) in raka materničnega telesa (za 1,4 %).
- Incidenčna stopnja raka materničnega vratu od uvedbe Državnega programa zgodnjega odkrivanja predrakavih sprememb in raka materničnega vratu (ZORA) pada (za povprečno 0,7 % na leto v zadnjih desetih letih).
- Podobno kot pri moških se tudi pri ženskah zaradi uvedbe presejalnega programa Svit leta 2009 spreminja časovni trend pojavljanja raka debelega črevesa in danke – od leta 2012 groba incidenčna stopnja pada za 1,4 % letno, pred tem pa je med 1999 in 2008 naraščala vsako leto za 3,4 %.

Redki raki

- Poseben izziv so redke rakave bolezni (opredeljene kot tiste, ki se jih letno diagnosticira manj kot 6 novih primerov na 100.000 prebivalcev).
- Skupaj so redki raki v Sloveniji predstavljali približno petino vseh novo ugotovljenih primerov raka – letno je za njimi zbolelo približno 3.000 bolnikov.
- Za redke rake je značilno, da se v primerjavi s pogostejšimi večkrat pojavljajo pri otrocih in mladostnikih.
- Kot pri vseh redkih boleznih se tudi pri redkih rakah spopadamo s podobnimi težavami: pozno in težko jih diagnosticiramo, njihov nastanek in možnosti zdravljenja so slabo raziskani ali pa najustreznejše zdravljenje ni široko dostopno. Da bi uspešno obvladovali redke rake, je pomembno, da njihovo breme natančno spremljamo ter da vse države sprejmejo smernice in določijo referenčne centre za diagnostiko in zdravljenje teh bolnikov.

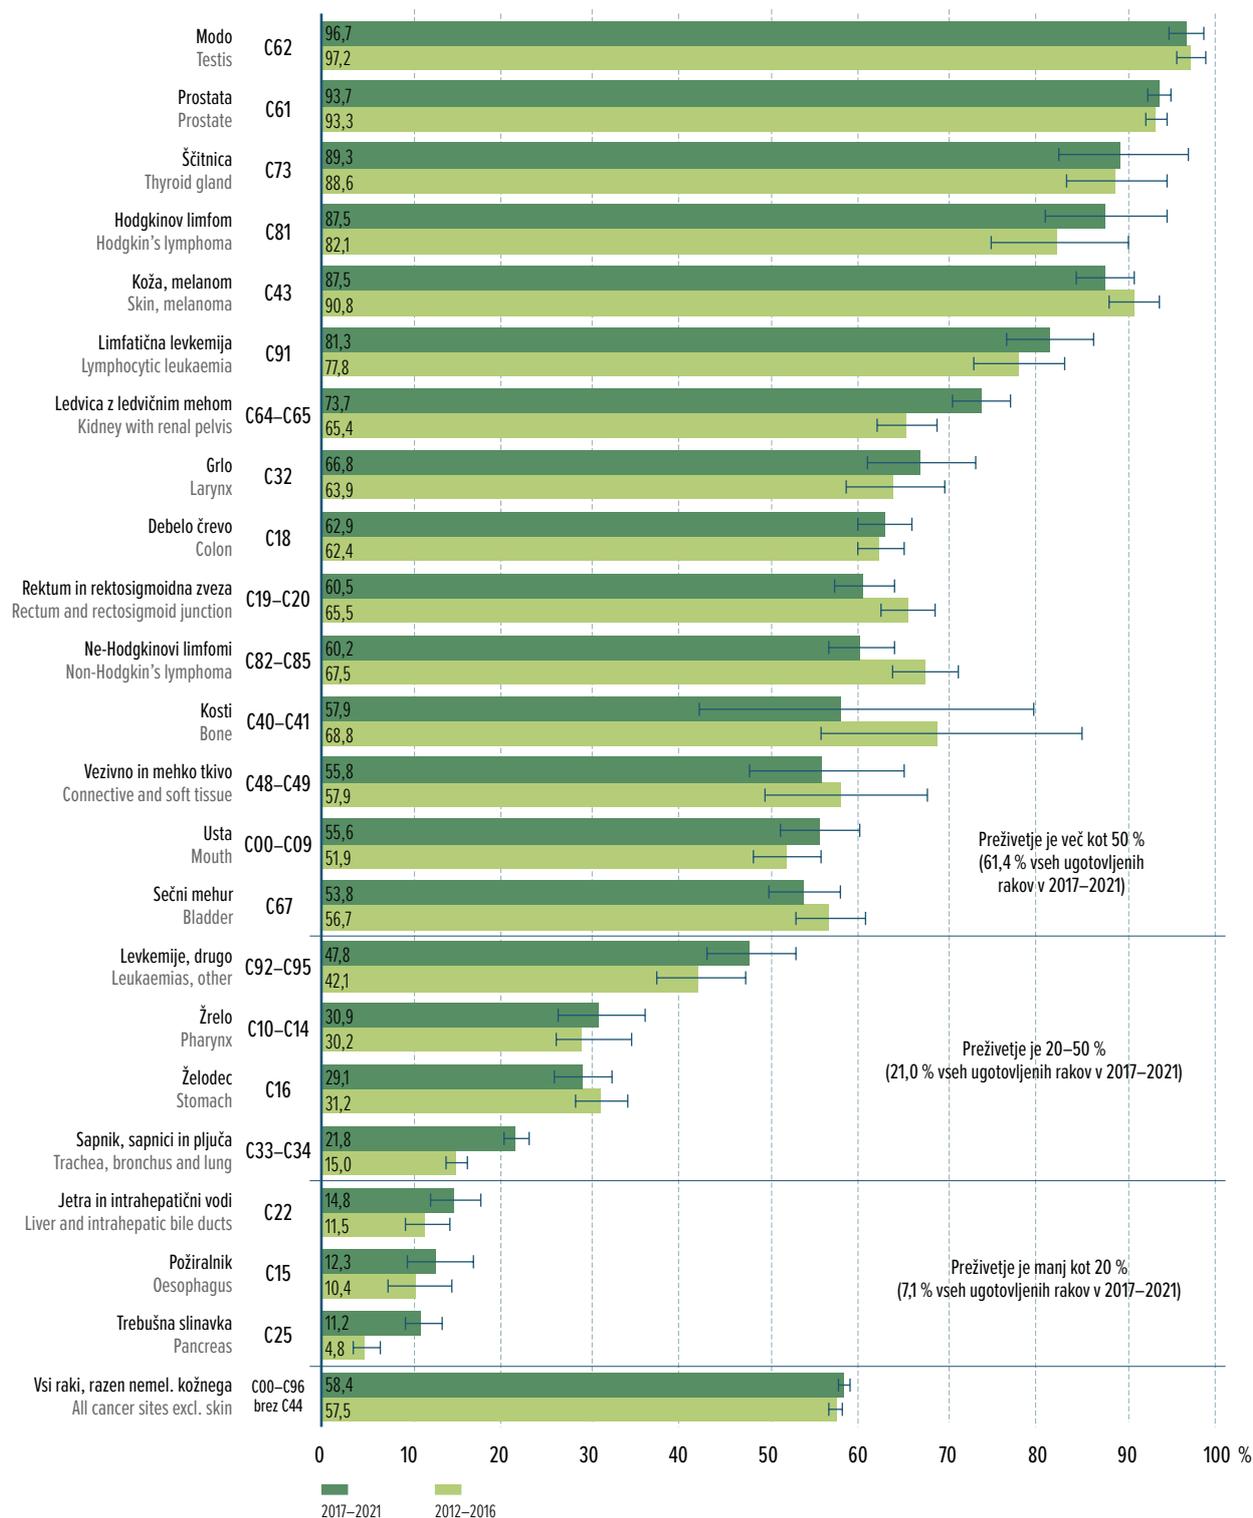

Preživetje

- Petletno čisto preživetje moških bolnikov s katerokoli vrsto raka razen nemelanomskega kožnega, ki so zboleli v obdobju 2017–2021, je bilo že 58,4 %, pri ženskah pa 62,7 %.
- Več kot 80 % je bilo čisto petletno preživetje pri moških z rakom mod, prostate, ščitnice, kožnim melanomom in Hodgkinovim limfomom, pri ženskah pa pri bolnicah z rakom ščitnice, kožnim melanomom, rakom dojk in Hodgkinovim limfomom.
- Statistično značilen napredek je pri obeh spolih v zadnjih petih letih opazen pri pljučnem raku, kjer je petletno preživetje pri moških že preseglo 30 %.
- V letu 2020 je bil narejen pregled preživetij slovenskih onkoloških bolnikov, zbolelih med letoma 1997 in 2016. Rezultati analize so na voljo v publikaciji *Preživetje bolnikov z rakom, zbolelih v letih 1997–2016 v Sloveniji* (Zadnik et al., 2020), ki je v digitalni obliki dostopna na www.onko-i.si/rrs. Glavni zaključki so:

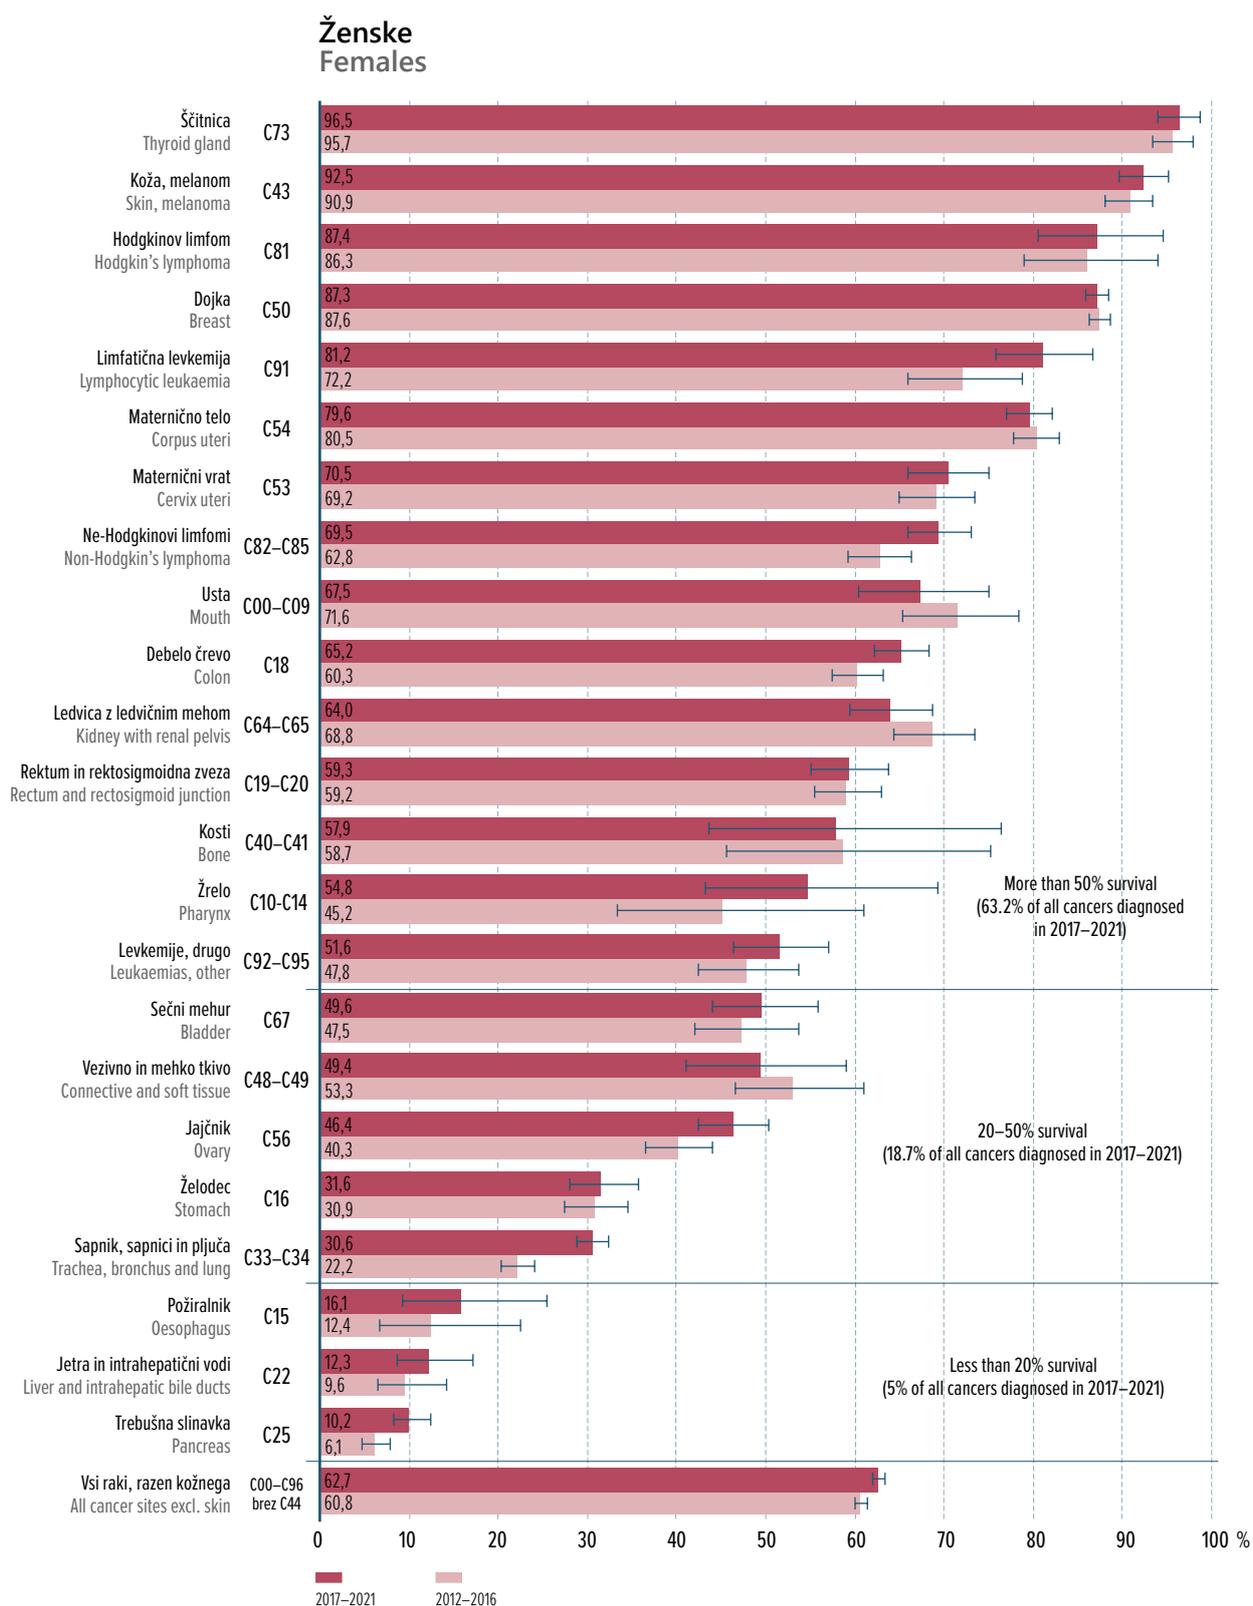

1. Preživetje slovenskih bolnikov z rakom se s časom povečuje. V zadnjih 20 letih (1997–2001 in 2012–2016) se je petletno čisto preživetje povečalo za 11 odstotnih točk. Občutno večja je rast pri moških, kjer se je petletno čisto preživetje povečalo za 17 odstotnih točk (z 38 % na 55 %). Pri ženskah je petletno čisto preživetje zraslo za 6 odstotnih točk (s 54 % na 60 %).
2. Ključni dejavniki za preživetje bolnikov z rakom so še vedno starost, stadij ob diagnozi in ustrezno zdravljenje. Petletno čisto preživetje je najmanjše pri starejših od 75 let, vendar se je tudi v skupini najstarejših bolnikov v zadnjih 20 letih petletno preživetje izboljšalo za 7 odstotnih točk. Petletno čisto preživetje bolnikov z omejenim stadijem se je v 20 letih povečalo za 10 odstotnih točk; preživetje pri bolnikih z razsejanim stadijem se ne izboljšuje.
3. Pri obeh spolih se je v zadnjih 20 letih značilno povečalo preživetje pri treh pogostih rakih: raku na debelem črevesu in danki (za 14 odstotnih točk z 48 % na 62 %), kožnem melanomu (za 12 odstotnih točk z 79 % na 91 %) ter pri pljučnem raku (za 8 odstotnih točk z 10 % na 18 %). Rezultati kažejo zgodnejšo diagnostiko in napredek pri sistemskem zdravljenju.
4. Občuten je tudi napredek pri obeh najpogostejših rakih, raku dojk pri ženskah in raku prostate pri moških: petletno čisto preživetje bolnic z rakom dojk se je v zadnjih 20 letih povečalo za 10 odstotnih točk, petletno čisto preživetje bolnikov z rakom prostate pa celo za več kot 20 odstotnih točk. Velik napredek pri raku prostate je verjetno samo navidezen, saj smo ravno v obravnavnem obdobju v Sloveniji precej nekritično uporabljali testiranje PSA, s katerim smo odkrivali rake prostate, ki bi po naravnem poteku še dolgo ostali klinično nemi, ter tako z zgodnejšo diagnozo umetno podaljšali preživetje.
5. V skupino rakov, kjer napredka s časom ni opaziti ter pri katerih preživetje še vedno ostaja slabo, pa se uvrščajo rak trebušne slinavke, rak požiralnika, raki jeter, žolčnika in žolčevodov ter možganski tumorji.
6. V raziskavi CONCORD-3 smo primerjali petletna čista preživetja odraslih bolnikov, zbolelimi med letoma 2010 in 2014 v 26 evropskih državah, s 15 različnimi vrstami raka. Preživetje slovenskih bolnikov z rakom je v večini primerov pod evropskim povprečjem, kar nam daje dobro osnovo za nadaljnje izboljšave.
7. Med bolniki z rakom je manj kot 1 % otrok in mladostnikov; zbolevalo predvsem za levkemijami, tumorji osrednjega živčevja in limfomi in imajo boljše petletno preživetje kot odrasli. V zadnjih 20 letih (1997–2001 in 2012–2016) se je petletno preživetje otrok in mladostnikov, zbolelih za rakom, povečalo za 7 odstotnih točk (z 79 % na 86 %).

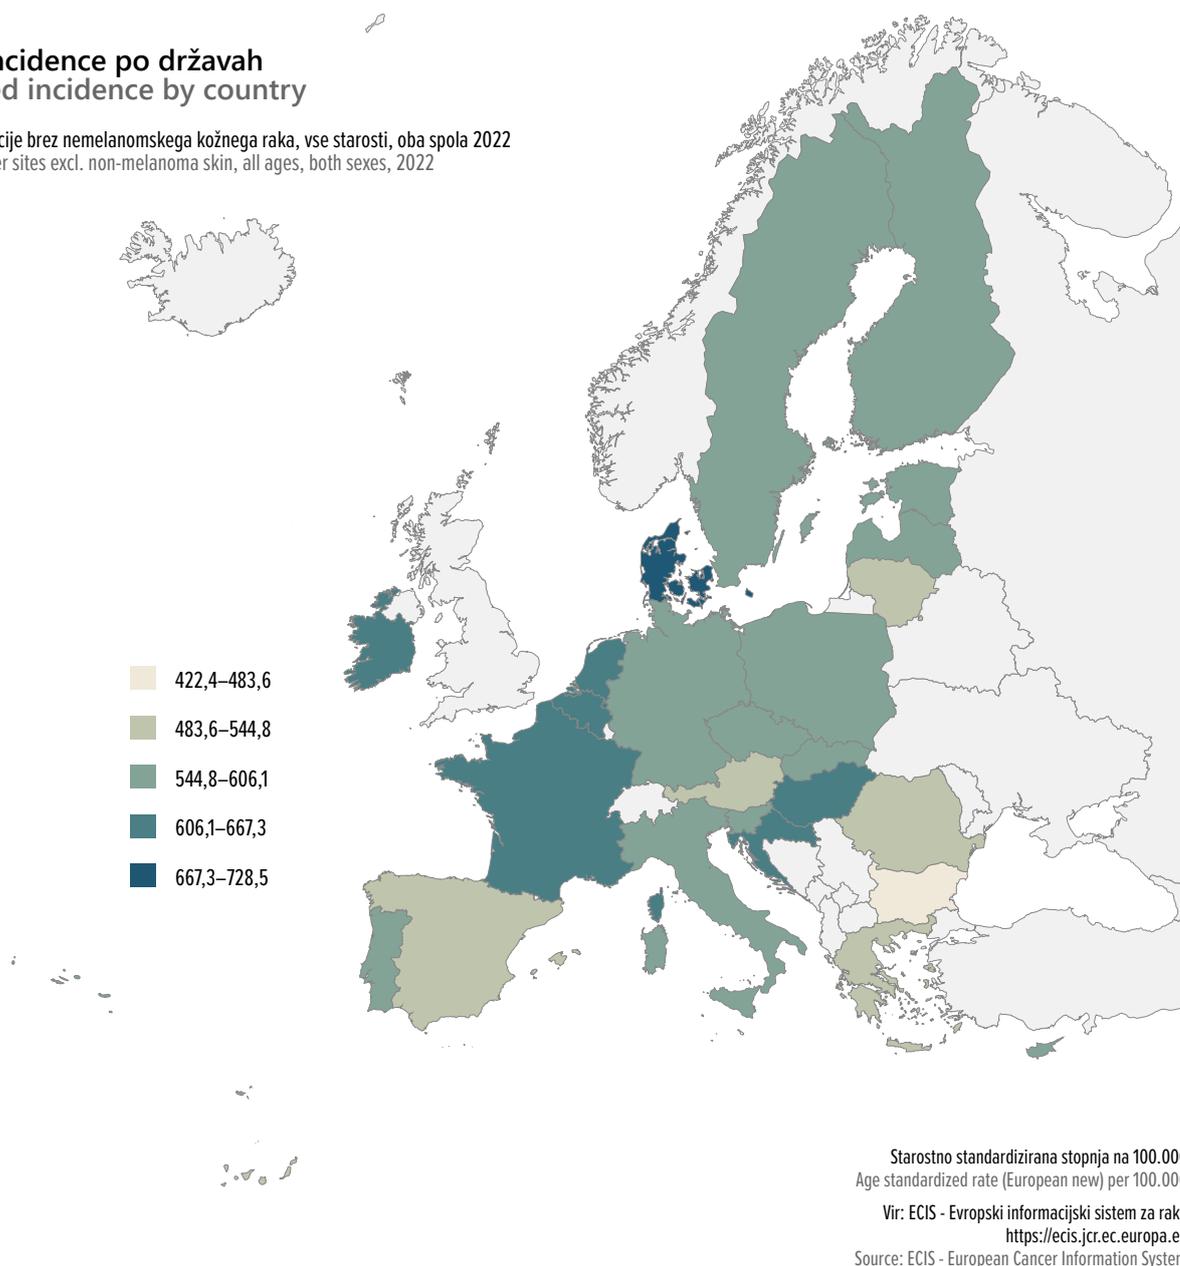

Figure 9b. Five-year net survival (with 95% confidence interval) for females diagnosed with selected cancers in periods 2017-2021 and 2012-2016.

Primerjava z Evropo

- Po ocenah Evropskega informacijskega sistema za raka (<https://ecis.jrc.ec.europa.eu/>) je bila Slovenija leta 2022 po incidenčni stopnji (starostno standardizirani na evropsko prebivalstvo) vseh rakov razen kožnega (605/100.000) na osmem mestu med 27 evropskimi državami. Večjo incidence so imele Danska, Irska, Nizozemska, Hrvaška, Madžarska, Belgija in Francija.
- Po umrljivostni stopnji smo na petem mestu, večjo umrljivost so imele Poljska, Madžarska, Hrvaška in Slovaška.

Cancer in Slovenia

For additional information on the burden of cancer in Slovenia and in the world, visit: www.slora.si/en. Figures are available on pages 15–27.

Summary

- Among those born in 2021, one in two men and one in three women are expected to develop cancer by the age of 75.
- Every year around 17,000 Slovenians (more than 9,000 men and more than 8,000 women) are diagnosed with cancer and over 6,000 (about 3,500 men and 2,500 women) die of cancer. Currently, there are already over 130,000 people living in Slovenia who have at some point during their lifetime been diagnosed with cancer (prevalence).
- The number of new cases in 2021, in the second year of the Covid-19 epidemic, is much higher compared to the first year of the epidemic, but we still did not make up for the shortfall from 2020.
- The risk of developing cancer increases gradually with age and is highest among the elderly population; of all cancer patients diagnosed in 2021, 66% were over 65 years old. As the Slovenian population is ageing, the number of new cancer cases is expected to increase simply on account of the growing proportion of elderly people.
- In 2021, the most frequent cancers in Slovenia (skin, lung, breast, prostate, and colorectal) accounted for 60% of all diagnosed cancers. These cancers are associated with unhealthy lifestyle: smoking, alcohol consumption, unhealthy diet, lack of physical activity, overweight and obesity, and excessive sun exposure – primary prevention measures should be in place with the aim to reduce their burden.
- Cancer screening programmes recommended by the Council of the European Union (EC) that have been introduced in Slovenia could lower mortality from breast, colorectal and cervical cancer through early detection; in addition cancer incidence for colorectal and cervical cancers has already been reduced.
- The five-year net survival of adult Slovenian patients with any type of cancer (excluding non-melanoma skin cancer) who were diagnosed in the 2017–2021 period was 58% in men and 63% in women.

Basic figures on cancer in Slovenia 2021

- In 2021, 17,286 people (9,317 men and 7,969 women) were diagnosed with cancer in Slovenia.
- The age-standardized incidence rate (European standard population) was 516.9/100,000; 589.0 in men and 459.2 in women. Among those born in 2021, one in two men and one in three women are expected to develop cancer by the age of 75.
- In 2021, 6,213 Slovenians died of cancer, 3,555 men and 2,658 women. There were 130,636 people alive in Slovenia (60,563 men and 70,073 women) who had at some point during their lifetime been diagnosed with cancer (prevalence).
- There are no significant differences in the burden of cancer between regions of Slovenia.

Age of patients

- Although the risk of cancer increases gradually with age, it is by far highest in older age; of all cancer patients in 2021, as many as 69% men and 64% women were diagnosed with cancer after the age of 65. Less than half a percent of all cancers were diagnosed in children and adolescents (up to 20 years of age).

- As the Slovenian population is ageing, the number of new cancer cases is expected to increase simply on account of the growing proportion of elderly people. We estimate that in 2023, there will have been as many as 17,971 newly diagnosed cancer patients.

Time trends

- The number of new cases in 2021, in the second year of the Covid-19 epidemic, is much higher compared to the first year of the epidemic, but we still did not make up for the shortfall from 2020.
- The crude incidence rate has almost doubled in the last twenty years, increasing by an average of 1.9% per year over the last decade (by 1.4% in men and 2.5% in women). The crude mortality rate has increased on average by 0.5% per year in men over the last 10 years and by 0.7% in women.
- More than half of this increase can be attributed to an ageing population, as longer life expectancy means more people are likely to be diagnosed with cancer. The age-standardized, cumulative incidence rate shows that the risk of cancer adjusted for ageing has been increasing more slowly, with the trend reversed for men. It is also encouraging that cancer mortality (if we adjust for ageing) has been declining, especially since the mid-1990s, pointing to greater successes of cancer treatment.

Most frequent cancers

- Cancer is not a single disease, but rather several hundred different diseases. These can occur in all tissues and organs of the human body. They vary in frequency, treatment and outcome, and are also associated with different, more or less established risk factors.
- The five most frequent cancers in Slovenia – skin (excluding melanoma), lung, breast, prostate and colorectal – account for 60% of all new cancer cases.
- The most frequent cancers are associated with an unhealthy lifestyle, excessive sun exposure, unhealthy diet, smoking and alcohol consumption. Primary prevention measures should be in place with the aim to reduce their burden.
- In men, prostate cancer and non-melanoma skin cancer account for around one-fifth of all cancers each, followed by lung and colorectal cancer. In women, non-melanoma skin cancer is the most frequent cancer, followed by breast cancer, which accounts for one-fifth of all cancer cases. The next most frequent cancers in women are colorectal and lung cancer.
- The most frequent cancers differ according to age. In children and adolescents aged under 20 years leukaemias are the most frequent, followed by tumours of the central and autonomic nervous system and lymphomas. Young adult men are most often diagnosed with testicular cancer and skin cancer, while in young women breast cancer is ranked first.

Time trends for most frequent cancers

- Among the more frequent cancers in men, the incidence rate of lung cancer was increasing until the early 2000s, when it stabilized at around 90/100,000.
- In the new millennium lung cancer is being overtaken by prostate cancer and non-melanoma skin cancer which is still increasing at an average rate of 5% per year. The dramatic increase in the incidence of prostate cancer over the past two decades is not due to any newly identified risk factor, but rather to the increasing use of the prostate-specific antigen (PSA) test in healthy men and therefore detection of a large number of cancers that would have otherwise remained

undetected for life. Data for recent years indicate that we have already reached the peak incidence of prostate cancer.

- Time trends in the incidence of colorectal cancer must also be interpreted by taking into account changes in diagnostics – in 2009 Slovenia introduced the national screening and early detection programme for colorectal cancer (Svit). The crude incidence rate of colorectal cancer in men decreased by 1.9% per year from 2012 on, but it was on the rise in 1999–2008 (3.6% on average annually). Average annual percentage changes are shown next to the incidence curves in Figure 7.
- Among the more frequent cancers in women, crude incidence rates have been increasing for breast cancer (by 1.9% on average per year), skin, excluding melanoma (by 5.3% on average per year), lung cancer (by 6.0% on average per year) and corpus uteri cancer (by 2.7% on average per year).
- The incidence rate of cervical cancer has decreased significantly since the introduction of the national cervical cancer screening programme (ZORA) (by an average of 0.7% per year in the last ten years).
- Similar to men, the introduction of the Svit screening programme in 2009 has had an impact on the time trend of colorectal cancer in women – the crude incidence rate of colorectal cancer in women decreased by 1.4% per year from 2011 on, but it was on the rise in the 1999–2008 period (3.4% on average annually).

Rare cancers

- A particular challenge is posed by rare cancers (defined as those with less than six new cases per 100,000 per year).
- In total, rare cancers in Slovenia accounted for about a fifth of all newly diagnosed cancers – around 3,000 patients were diagnosed with rare cancers every year.
- As opposed to frequent cancers, rare cancers are more likely to occur in children and adolescents.
- Problems with rare cancers are similar to those characteristic of all rare diseases: they are difficult to diagnose and are often detected late, their aetiology and treatment options are poorly researched, or else the most appropriate treatment is hard to access. In order to successfully manage rare cancers, it is important that their burden is closely monitored, and that all countries adopt guidelines as well as establish reference centres for diagnostics and treatment of such patients.

Survival

- The five-year net survival of male patients with any type of cancer excluding non-melanoma skin cancer diagnosed between 2017 and 2021 was 58.4%, while in women it was 62.7%.
- The five-year net survival was over 80% in men with testicular cancer, prostate cancer, thyroid cancer, skin melanoma and Hodgkin's lymphoma, and in women with thyroid cancer, skin melanoma, breast cancer and Hodgkin's lymphoma.
- Statistically significant progress has been observed for both sexes in the last five years in lung cancer, where five-year survival in men has already exceeded 30%.
- In 2020, a survival analysis of Slovenian cancer patients diagnosed between 1997 and 2016 was performed. The results of the analysis are published in the publication *Survival of Cancer Patients, Diagnosed in 1997–2016 in Slovenia* (Zadnik et al., 2021) which is also available in digital format at www.onko-i.si/eng/crs. The main conclusions are on the next page.

1. Survival of Slovenian cancer patients is improving over time. During the 20 years observed (1997–2001 and 2012–2016), five-year net survival increased by 11 percentage points. The increase was significantly higher in men, for whom five-year net survival increased by 17 percentage points (from 38% to 55%). In women, five-year net survival increased by 6 percentage points (from 54% to 60%).
2. Age and stage at diagnosis are still key factors when it comes to survival of cancer patients. Five-year net survival is lowest in those aged 75–94, though even in this age group it has improved by 7 percentage points over the past 20 years. Five-year net survival of patients with localized disease increased by 10 percentage points over the observed 20 years and has reached 85% during the last period; survival of patients with distant disease has not improved.
3. For both sexes combined, survival has improved significantly over the last 20 years for the three most frequent cancers: colorectal cancer (by 14 percentage points, from 48% to 62%), skin melanoma (by 12 percentage points, from 79% to 91%), and lung cancer (by 8 percentage points, from 10% to 18%). This improvement is due to earlier diagnosis and advances in systemic treatment.
4. Progress has also been shown in the two most frequent cancers by sex: breast cancer in women and prostate cancer in men. The five-year net survival of breast cancer patients has increased for 10 percentage points in the last 20 years, while the five-year net survival of prostate cancer patients has increased for over 20 percentage points. The improvement in prostate cancer survival is probably not real, since in the period under review, PSA testing in Slovenia was performed rather uncritically and likely resulted in detection of prostate cancers that would have otherwise remained clinically silent for a long time, thus artificially prolonging survival on account of earlier diagnosis in the natural course of disease.
5. The group of cancers where no progress has been observed over time and where survival still remains low includes pancreatic cancer, oesophageal cancer, liver, gallbladder and bile duct cancers as well as brain tumours.
6. In the CONCORD-3 study, five-year net survival of adult patients with 15 different cancers diagnosed between 2010 and 2014 was compared among 26 European countries. In most cases survival rates of Slovenian cancer patients are below the European average, which highlights the need and serves as an incentive for future improvements.
7. Less than 1% of cancer patients are children and adolescents; they are mainly diagnosed with leukaemias, central nervous system tumours and lymphomas, and have a better five-year survival compared to adults. In the last 20 years (1997–2001 and 2012–2016), the five-year survival of children and adolescents with cancer has increased by 7 percentage points (from 79% to 86%).

Comparisons with Europe

- In 2022, according to the estimates of the European Cancer Information System (<https://ecis.jrc.ec.europa.eu/>) Slovenia ranked eighth among 27 European countries with respect to the incidence rate (age standardized, European population standard) of all cancers excluding skin cancer (605/100,000). Denmark, Ireland, the Netherlands, Croatia, Hungary, Belgium and France had a higher incidence.
- We are in fifth place in terms of mortality, led by Poland, Hungary, Croatia and Slovakia.
